Two Weeks Ago

1. [**Learnable Alpha**] *Hypothesis*: Raw alpha logit is diverging → final value converges to 0.1
   - Modify alpha's activation function that prevents divergence + known stable behavior at 0
2. [**Learnable Alpha**] Loading a pretrained Euclidean checkpoint + initialize alpha at 0.0
3. [**Learnable Alpha**] Loss ablation test similar to table 5 of the paper
   - *Hypothesis*: Not all losses should use the Finsler distance function or need special care
4. [**Learnable Omega**] Brainstorm and implement architecture to learn drift vector omega
   - Right now the model can only model asymmetry if the "domain shift" happens to align perfectly with the last dimension OR learn to compress all asymmetry to the last dimension

Learnable Alpha – Model Introduction

Alpha Parameter

$0 < \alpha_{max} < 1$ be the maximum scaling factor (default 1.0).

$\rho \in R$ be the **learnable** logit parameter.

$$\alpha = 2 \cdot \boxed{\alpha_{max}} \cdot \left| \boxed{\sigma} \left(\frac{\boxed{\rho}}{\boxed{T}} \right) - 0.5 \right|$$

$\sigma(z) = \dfrac{1}{1 + e^{-z}}$ be the sigmoid function.

$T > 0$ be the temperature scaling factor (default 1.0).

Link to interactive graph

Starting point (original α parameterization)#

- Used a *centered / symmetric* mapping:
- Design goal: **Euclidean baseline at raw=0 ⇒ α=0**
    - Observed issue: **raw=0 becomes a "valley/saddle"**; training can **stick near α≈0** (α doesn't "turn on"), especially when initialized exactly at 0.

Learnable Alpha – Model Introduction

Quantitative Results

Empirical symptom (α-init sweep)

- When initializing **α > 0**, many runs tended to **move toward a small α band** (≈0.1-ish early observations).
- When initializing **α = 0**, α often **failed to leave 0** (or moved very differently), even **without pretrained weights**.
- Interpretation discussed: **gradient starvation / symmetry not broken** → the backbone learns a Euclidean solution that provides little useful signal to grow α.

Learnable Alpha – Model Introduction
Quantitative Results

Alpha values converging lower

- **Old System (Sigmoid):** To reach $\alpha = 0$ (Euclidean baseline), the raw parameter had to be pushed towards $-\infty$. As the value got smaller (e.g., reaching 0.1), the gradients of the sigmoid function naturally vanished. The optimizer essentially "ran out of gas" at 0.1, unable to push the value any lower. 0.1 was likely a **false floor** caused by gradient saturation.
- **New System (Centered):** To reach $\alpha = 0$, the raw parameter simply needs to be 0. The gradient at this point is healthy and non-zero. The model is now free to go lower than 0.1 because the mathematical resistance has been removed.

Pretrained checkpoint behavior

- Loading a **Euclidean pretrained BAU** made it even more likely that α would not increase meaningfully.
- Hypothesis: the embedding space is already optimized for Euclidean distances; turning on asymmetry **initially harms loss**, so α gets no consistent push.

Activation-function brainstorming (goal: keep "stable point" at raw=0 but

avoid dead gradient)

- Considered switching to back **monotonic sigmoid** mapping but clamped the alpha init at 1e-3 (e.g., if we initialize alpha at 0)
- Observed result: In practice, "α-init=0.001" still produced **very negative raw** (≈ −9), pushing sigmoid into **saturation** ⇒ gradients effectively **near-zero** again.
  Net effect: **still "dead" / stuck** (function not helping escape the valley).

Optimizer-side mitigation discussed

- Proposed: **separate optimizer parameter group for α**
  - **Higher LR** for α (e.g., ×100)
  - **No weight decay** on α
- Rationale: α is a single scalar competing with millions of backbone params; needs stronger step size and fewer regularization forces.
- Observation: α converged to zero, performance still subpar

Learnable Alpha – Loss Ablation Study

Introducing the Loss Configurations

Loss Names	Loss Configurations	Aug. Prob.
1_Abs_Baseline	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}}$	0
2_Pure_Triplet	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{tri}}$	0.5
3_Std_Baseline	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}}$	0.5
4_CE_Align	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{align}}$	0.5
5_Base_Align	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}} + \mathcal{L}_{\text{align}}$	0.5
6_Base_Uniform	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}} + \mathcal{L}_{\text{uniform}}$	0.5
7_Base_Domain	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}} + \mathcal{L}_{\text{domain}}$	0.5
8_Base_Align_Uni	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}} + \mathcal{L}_{\text{align}} + \mathcal{L}_{\text{uniform}}$	0.5
9_Base_Align_Dom	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}} + \mathcal{L}_{\text{align}} + \mathcal{L}_{\text{domain}}$	0.5
10_Base_Uni_Dom	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}} + \mathcal{L}_{\text{uni}} + \mathcal{L}_{\text{domain}}$	0.5
11_Full_Method	$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{CE}} + \mathcal{L}_{\text{tri}} + \mathcal{L}_{\text{align}} + \mathcal{L}_{\text{uni}} + \mathcal{L}_{\text{domain}}$	0.5

For the finsler model, we set the following hyperparameters:
ALPHA_INIT=0.1 | ALPHA_MAX=1.0 | ALPHA_TEMP=1.0

To strictly evaluate the impact of the learnable Finsler parameter (alpha) on the backbone's behavior, we avoid the complex regularizers (Align, Uniform, Domain) initially and slowly re-introduce them.

- This isolates whether alpha is aiding the core metric learning (Triplet) or the regularization tasks.

Why alpha_init = 0.1?

- **Convergence Evidence:** The alpha/raw line chart is the most telling. Runs initialized at high values (0.9, 0.7, 0.5) all rapidly collapse and converge towards the **0.1 - 0.2 range**. This suggests the model naturally prefers a small amount of asymmetry but rejects strong asymmetry.
- **Performance & Stability:** The scatter plot ("Effect of Finsler alpha") shows a distinct peak in mean mAP and Rank-1 at 0.1.
- **The "Cold Start" Problem:** The run initialized at 0.0 (grey line) stays very flat near zero. Since alpha acts as a multiplier in the distance addition, if it starts at exactly 0.0, the gradients might be too weak to nurture it away from the Euclidean saddle point. Starting at 0.1 places the parameter in the "active" zone immediately, which should actually **reduce variance** by preventing runs from getting "stuck" in Euclidean space.

1. **Absolute Baseline (No Augs):** ($L_{ce} + L_{tri}$.(The control variable.
2. **Pure Metric:** (L_{tri} only). Critical check: Does alpha help ranking when classification loss (L_{ce}) is removed?
3. **Standard ReID:** ($L_{ce} + L_{tri}$ + Augmentations). The standard baseline for modern ReID.
4. **Base + Align:** Adds geometric alignment. Does alpha help align variations?
5. **Base + Uniform:** Adds uniformity. Does alpha help spread features?
6. **Base + Domain:** Adds domain adaptation. Does alpha help bridge domains?
7. **Base + Align + Uniform:** Testing the core "BAU" hypothesis without Domain loss.
8. **Base + Align + Domain:** Testing alignment consistency across domains.
9. **Base + Uniform + Domain:** Testing distribution shape across domains.
10. **Full Method:** All losses enabled.

Learnable Alpha – Loss Ablation Study

Quantitative Results – Rank 1 and mAP

1. **Finsler (learnable α) does not improve overall performance.**
   Across most configurations, Finsler is worse than Euclidean, sometimes substantially (e.g., CE + Align, Base + Align, Base + Align + Uni). The only clear exception is Base + Align + Domain, where Finsler is slightly better.
2. **α behavior is unstable and often saturates.**
   Final α values collapse to 1.0 for many configs (Std Baseline, CE+Align, Base+Align, Base+Uni, Base+Dom, Base+Align+Uni, Base+Uni+Dom). This saturation correlates with performance drops, suggesting the model over-activates asymmetry without benefiting discriminability.
3. **When Finsler performs well, α is near 0.0.**
   The best Finsler results align with α≈0 (e.g., Full Method, and Base+Align+Dom with α≈0.027). This implies the model prefers Euclidean geometry for most loss combinations.
4. **Align loss is harmful under Finsler.**
   Configs that include Align (especially CE+Align and Base+Align) degrade sharply with learnable α, indicating incompatibility between alignment regularization and asymmetric distance (at least in the current formulation).
5. **(Triplet-only does not benefit from Finsler.)**

(Pure Triplet is slightly worse under Finsler, indicating α does not provide a stable metric advantage in isolation.)

Learnable Alpha – Loss Ablation Study
Conclusions

1. **Finsler (learnable α) does not improve overall performance.**
   Across most configurations, Finsler is worse than Euclidean, sometimes substantially (e.g., CE + Align, Base + Align, Base + Align + Uni). The only clear exception is Base + Align + Domain, where Finsler is slightly better.
2. **α behavior is unstable and often saturates.**
   Final α values collapse to 1.0 for many configs (Std Baseline, CE+Align, Base+Align, Base+Uni, Base+Dom, Base+Align+Uni, Base+Uni+Dom). This saturation correlates with performance drops, suggesting the model over-activates asymmetry without benefiting discriminability.
3. **When Finsler performs well, α is near 0.0.**
   The best Finsler results align with α≈0 (e.g., Full Method, and Base+Align+Dom with α≈0.027). This implies the model prefers Euclidean geometry for most loss combinations.
4. **Align loss is harmful under Finsler.**
   Configs that include Align (especially CE+Align and Base+Align) degrade sharply with learnable α, indicating incompatibility between alignment regularization and asymmetric distance (at least in the current formulation).
5. **(Triplet-only does not benefit from Finsler.)**
   (Pure Triplet is slightly worse under Finsler, indicating α does not provide a stable metric advantage in isolation.)

Overall Interpretation
The current Finsler formulation does not generalize better than Euclidean in this BAU ablation. The only positive signal is **Base + Align + Domain**, where Finsler slightly helps with low α.

Bottom-line takeaway
Two failure modes were observed:

- **α stays near 0** (no symmetry breaking / no gradient signal).
- **α runs to 1.0** (unstable coupling → worse performance).

Fixing this likely needs **both** (a) better α parameterization/regularization **and** (b) optimizer treatment (LR/WD) so α learns on an appropriate timescale.

Moving Forward

- **Constrain α** (prevent saturation), or
- **Couple α to specific losses only**, or
- **Rework the drift term so that α>0 is actually beneficial** under alignment/regularization.
- Small learning rate on alpha

Learnable Alpha – Better Without Uniform Loss?

NOTE: It might be the same for the Euclidean case too! Ablation study did not cover this

Table 5: Ablation study of loss functions for augmented images.

Method	M+MS+CS → C3		M+CS+C3 → MS		MS+CS+C3 → M		Average	
	mAP	Rank-1	mAP	Rank-1	mAP	Rank-1	mAP	Rank-1

Today

1. [**Learnable Omega**] Brainstorm and implement architecture to learn drift vector omega
   - Implement some fix such that the model is more responsive to alignment loss
2. [**Visualisation**]
   - We could plot pairs of images that have the highest magnitude of omega, and pairs with the smallest magnitude
   - Reduce the IDs in the query so that it is more manageable (perhaps only 10-15)
   - Find a way to keep these IDs always the same across runs (just for the visualization), and not dependent on how the dataset is shuffled given the seed
3. [**Dataset**] Integrate cross-view dataset AG-ReID v2

Problem Motivation: Why Asymmetry in Re-ID?

Symmetric Distances

$$d(\mathbf{x}_{\mathrm{UAV}}, \mathbf{y}_{\mathrm{CCTV}}) = d(\mathbf{x}_{\mathrm{CCTV}}, \mathbf{y}_{\mathrm{UAV}})$$

Asymmetric Distances

$$d(\mathbf{x}_{\mathrm{UAV}}, \mathbf{y}_{\mathrm{CCTV}}) \neq d(\mathbf{x}_{\mathrm{CCTV}}, \mathbf{y}_{\mathrm{UAV}})$$

The information available for matching depends on the viewpoint of the query — the distance should reflect this

Recap: Original BAU

Learnable Omega – Architecture Introduction

- drift head: Receives pre-BN-neck features (preserves magnitude info)
- classifier: "Identity-only (no drift influence on classification)"

Learnable Omega – Model Introduction

Drift Branch

$$d_F(\mathbf{x}, \mathbf{y}) = \underbrace{\|\mathbf{x}_{\text{id}} - \mathbf{y}_{\text{id}}\|_2}_{\text{identity distance}} + \underbrace{\omega_{\mathbf{x}} \cdot (\mathbf{y}_{\text{id}} - \mathbf{x}_{\text{id}})}_{\text{viewpoint-dependent drift}}$$

Given an embedding $x \in \mathbb{R}^{4096}$

$x_{\text{id}} \in \mathbb{R}^{2048}$ Identity Feature *"Who is this?"*	$w_x \in \mathbb{R}^{2048}$ Drift Vector *"E.g., What Viewpoint?"*

- w_x is norm-constrained: $\|w\| \leq 0.95$
- $d_F(x, y) \neq d_F(y, x)$: asymmetric ranking

Learnable Omega – Loss Functions

$$\mathbf{h} = \begin{bmatrix} \mathbf{f} \\ \omega \end{bmatrix} \in \mathbb{R}^{4096}$$

$$\mathcal{L}_{\text{align}} = \sum_{(i,j)\in\mathcal{I}_{\text{pos}}} \bar{w}_{ij} \|\tilde{\mathbf{f}}_i - \mathbf{f}_j\|_2^2$$

$$\mathcal{L}_{\text{uniform}} = \frac{1}{2}\left(\log\left(\frac{1}{|\mathcal{I}_{\text{data}}|}\sum_{(i,j)\in\mathcal{I}_{\text{data}}} e^{-2\|\mathbf{h}_i-\mathbf{h}_j\|_2^2}\right) + \log\left(\frac{1}{|\mathcal{I}_{\text{data}}|}\sum_{(i,j)\in\mathcal{I}_{\text{data}}} e^{-2\|\tilde{\mathbf{h}}_i-\tilde{\mathbf{h}}_j\|_2^2}\right)\right)$$

$$\mathcal{L}_{\text{domain}} = \log\left(\frac{\sum_i \sum_{j\in\mathcal{N}(\mathbf{h}_i)} e^{-2\|\mathbf{h}_i-\mathbf{c}_j\|_2^2}}{\sum_i N}\right) + \log\left(\frac{\sum_i \sum_{j\in\mathcal{N}(\tilde{\mathbf{h}}_i)} e^{-2\|\tilde{\mathbf{h}}_i-\mathbf{c}_j\|_2^2}}{\sum_i N}\right)$$

- Computationally, this means we force the **identity features** to be invariant to augmentation, but we *do not* constrain the drift vectors to be augmentation-invariant.

1. The Goal of Alignment (Invariance)
In standard Contrastive Learning or Re-ID (the "BAU" baseline), the **Alignment Loss** forces the embedding of a weakly augmented image (f_w (to be identical to the embedding of its strongly augmented version (f_s.(
Mathematically, it minimizes:

$$\| f_s - f_w \|^2 \to 0$$

If your embedding f contains a drift vector ω, this loss forces:

$$\omega_s \approx \omega_w$$

This means the network learns to output the **same drift vector** regardless of how the image is augmented (e.g., cropped, colored, erased).

2. The Goal of Finsler Drift (Asymmetry)
The purpose of the drift vector ω is to model **viewpoint asymmetry**.
Scenario: A UAV (drone) image looking down vs. a CCTV image looking straight.
The geometric distortion from UAV → CCTV is fundamentally different from CCTV → UAV.
Therefore, the drift ω_{UAV} must be different from ω_{CCTV} to capture this

directional relationship.

3. The Conflict
Deep learning augmentations (Random Crop, Random Erasing) simulate these viewpoint changes and occlusions.
If you enforce Alignment on ω: You force the network to say "The geometric bias of this image is the same, even if I crop out the background or change the aspect ratio." This effectively kills the drift mechanism, collapsing $\omega \to 0$ or a constant constant, reverting the space back to Euclidean geometry.
If you want useful Drift: The drift *must* be sensitive to the specific visual content (the specific crop/view). It *should* change when the view changes.

Next Week

1. [**Learnable Omega**]: Consider implementing different repulsive forces to enforce domain generalization (other than uniformity and domain loss).
   - *Idea*: Something similar to the Finsler stress loss
2. [**Learnable Omega**]: Introduce a modification to the triplet loss
   - Compute the triplet loss using the inverse triplet (p, a, n'), where the positive is now the anchor (reverse direction)
   - Minimize the sum of these directional losses
   - *Hypothesis*: Shapes the embedding space such that the drift "w" minimizes the retrieval error in both directions independently
3. [**Learnable Omega**]: Change the norm clamping of the omega norm to something smoother, e.g., log-barrier loss?
4. [**Experiment**]: Inspect the initialization of the drift layer, and experiment with other types of initialization
5. [**Experiment**]: Reduce the embedding size of the drift vector
